

PASSWORD MANAGER > BITWARDEN SEND

### Send from CLI

Ansicht im Hilfezentrum: https://bitwarden.com/help/send-cli/

#### Send from CLI

Bitwarden Send is available as a set of fully-featured CLI commands. This article documents the breadth of bw send commands, however Send is not a separate tool from the Bitwarden command-line Interface (CLI). Therefore, many of the commands, options, and concepts in the CLI documentation are relevant here.

```
Usage: bw send [options] [command] <data>
Work with Bitwarden sends. A Send can be quickly created using this command or subcommands can be used to fine-tune the Send
Arguments:
  data
                                    The data to Send. Specify as a filepath with the --file option
Options:
  -f, --file
                                    Specifies that <data> is a filepath
     --deleteInDays <days>
                                    The number of days in the future to set deletion date, defaults to 7 (default: "7")
  -d,
                                    Hide <data> in web by default. Valid only if --file is not set.

The name of the Send. Defaults to a guid for text Sends and the filename for files.
  --hidden
  -n, --name <name>
  --notes <notes>
                                    Notes to add to the Send.
  --fullObject
                                    Specifies that the full Send object should be returned rather than just the access url.
  -h, --help
                                    display help for command
Commands:
                                    List all the Sends owned by you
  list
                                    Get json templates for send objects
  template <object>
  get [options] <id>
                                    Get Sends owned by you.
  receive [options] <url>
                                    Access a Bitwarden Send from a url
  create [options] [encodedJson] create a Send
  edit [options] [encodedJson]
                                    edit a Send
  remove-password <id>
                                    removes the saved password from a Send.
  delete <id>
                                    delete a Send
```

Send's --help text

#### send

The send command is the master command used to access all Send-related subcommands:

```
Bash
bw send [options] [command] <data>
```

The send command can also be used as a shortcut to quickly create a Send, for example:

```
bw send "Fastest Send in the West."
```

will create a text Send with the contents Fastest Send in the West, and output the Send link. Or, for example:

```
Bash
bw send -f <path/to/file.ext>
```

will create a file Send with the specified file at the specified path and output the Send link.

#### **Options:**

- Use -n <name> or --name <name> to specify a name for the Send. If none is specified, name will default to the id for text Sends and file name for file Sends. For multi-word names, use quotations "<name>".
- Use -d <days> or --deleteInDays <days> to specify a deletion date for the Send (defaults to seven days if unspecified).
- Use ——maxAccessCount or —a to specify the maximum access count for the Send.
- Use --hidden to specify that a text Send require recipients to toggle visibility.
- Use --notes <notes> to add private notes to the Send. For multi-word notes, use quotations "<notes>".
- Use ——fullObject to output the full Send object as JSON rather than only the Send link (pair this option with the ——pretty option for formatted JSON).

#### Full example:

#### Bash

bw send -n "My First Send" -d 7 --hidden "The contents of my first Send."

#### create

The create command creates a Send. create allows more advanced configuration than using only bw send and takes encoded JSON for its argument:

#### Bash

bw send create [options] <encodedJson>

A typical workflow might look something like:

- 1. Use the template command (see details) to output the appropriate JSON template for your Send type.
- 2. Use a command-line JSON processor like jq to manipulate the outputted template as required.
- 3. Use the encode command (see details) to encode the manipulated JSON.
- 4. Use the create command to create a Send from the encoded JSON.

For example, to create a text Send:

#### Bash

bw send template send.text | jq '.name="My First Send" | .text.text="Secrets I want to share."' | b
w encode | bw send create

For example, to create a password-protected file Send:

## bw send template send.file | jq '.name="My File Send" | .type=1 | .file.fileName="paperwork.png" | .password="p@ssw0rd"' | bw encode | bw send create

For example, to create a password-protected file Send with an explicit deletion date. This example is broken out by operating system due to the way <a href="tel:ale.">deletionDate</a> should be specified:

#### ⇒ Windows

# \$delDate = (Get-Date).AddDays(14) | date -UFormat "%Y-%m-%dT%H:%M:%SZ" bw send template send.text | jq ".name=\`"My Send\`" | .text.text=\`"Secrets I want to share.\`" | .password=\`"password\`" | .deletionDate=\`"\$delDate\`"" | bw encode | bw send create

Notice in this example that the jq invocation must be wrapped in double quotes (" ") and use escapes (\) for each filter due to a nested date variable that configures a .deletionDate in the send.

#### ⇒ macOS

#### Bash

bw send template send.text | jq ".name=\"My Send\" | .text.text=\"Secrets I want to share.\" | .pas sword=\"mypassword\" | .deletionDate=\"\$(date -uv+14d +"%Y-%m-%dT%H:%M:%SZ")\"" | bw encode | bw se nd create

Notice in this example that the jq invocation must be wrapped in double quotes (" ") and use escapes (\) for each filter due to a nested date variable that configures a .deletionDate in the send.

#### ⇒ Linux

#### Bash

bw send template send.text | jq ".name=\"My Send\" | .text.text=\"Secrets I want to share.\" | .pas
sword=\"mypassword\" | .deletionDate=\"\$(date "+%Y-%m-%dT%H:%M:%SZ" -d "+14 days")\"" | bw encode |
bw send create

Notice in this example that the jq invocation must be wrapped in double quotes (" ") and use escapes (\) for each filter due to a nested date variable that configures a .deletionDate in the send.

#### **Options:**

- Use --file <path> to specify the file to Send (this can also be specified in encoded JSON).
- Use —-text <text> to specify the text to Send (this can also be specified in encoded JSON).
- Use --hidden to specify that a text Send require recipients to toggle visibility.
- Use --password <password> to specify the password needed to access password-protected.
- Use ——fullObject to output the full Send object as JSON rather than only the Send link (pair this option with the ——pretty option for formatted JSON).

#### get

The get command will retrieve a Send owned by you and output it as a JSON object. get takes an exact id value or any string for its argument. If you use a string, get will search your Sends for one with a value that matches:

#### Bash

bw send get [options] <id / string>

If you create a Send in another Bitwarden app while this session is still active, use the bw sync command to pull recent Sends. For more information, refer to our CLI documentation.

#### **Options:**

- Use —text to output only the text contents of a text Send.
- Use ——file to output only the file of a file Send. Pair ——file with ——output to specify a directory, or with ——raw to output to stdout.
- Use --output <output> to specify the output directory for the --file option.

#### edit

The edit command edits an existing Send. edit takes encoded JSON for its argument:

#### Bash

bw send edit <encodedJson>

A typical workflow might look something like:

- 1. Use the get command (see details) to retrieve the desired Send according to its <id>.
- 2. Use a command-line JSON processor like jq to manipulate the retrieved Send as required.
- 3. Use the encode command (see details) to encode the manipulated JSON.
- 4. Use the edit command to write the edits to the send.

For example:

#### Bash

bw send get <id> | jq '.name="New Name" | .password=null' | bw encode | bw send edit

#### **Options:**

• Use --itemid <itemid> to overwrite the id value provided of the Send with a new one.

#### (i) Note

You can't edit a file Send's file. To do this, you will need to delete the Send and re-create it with the appropriate file.

#### list

The list command will list all Sends owned by you and output them as JSON:

#### Bash

bw send list [options]

If you create a Send in another Bitwarden app while this session is still active, use the bw sync command to pull recent sends. For more information, refer to our CLI documentation.

#### **Options:**

- Use --pretty to format the JSON the output.
- Pipe stdout to a file using the > operator, for example:

#### Bash

bw send list --pretty > /Users/myaccount/Documents/pretty\_list\_of\_sends.json

#### delete

The delete command will delete a Send owned by you. delete takes only an exact id value for its argument.

#### Bash

bw send delete <id>

#### ∏ Tip

If you don't know the exact id of the Send you want to delete, use bw send get <search term> to find it.

#### template

The template command returns the expected JSON formatting for a Send object. template takes an <object> specification for its argument, either send.text or send.file.

#### Bash

bw send template <object>

While you can use template to output the format to your screen, the most common use-case is to pipe the output into a bw send crea te operation, using a command-line JSON processor like jq and bw encode to manipulate the values retrieved from the template, for example:

#### Bash

bw send template send.text | jq '.name="My First Send" | .text.text="Secrets I want to share."' | b
w encode | bw send create

#### receive

The receive command accesses a Send. receive takes a Send <url> for its argument:

#### Bash

bw send receive [options] <url>

• For text Sends, receive will return the text contents of the Send.

• For file Sends, receive will download the file to the current working directory.

#### **Options:**

- Use --password <password> to provide the password needed to access password-protected Sends as a string.
- Use —passwordenv <passwordenv> to specify the password needed to access password-protected Sends as a stored environment variable.
- Use ——passwordfile <passwordfile> to specify the password needed to access password-protected Sends as a file with the password as its first line.
- Use --obj to output the full Send object as JSON rather than only the Send link (pair this option with the --pretty option for formatted JSON).
- Use --ouput <output> to specify the output directory for the contents of a file Send.
